

Automatic Speech Recognition (I)

borrowing from
Daniel Jurafsky and James Martin

Outline for ASR

- ASR Architecture
 - The Noisy Channel Model
- Five easy pieces of an ASR system
 - 1) Language Model
 - 2) Lexicon/Pronunciation Model (HMM)
 - 3) Feature Extraction
 - 4) Acoustic Model
 - 5) Decoder
- Training
- Evaluation

Speech Recognition

- Applications of Speech Recognition (ASR)
 - Dictation
 - Telephone-based Information (directions, air travel, banking, etc)
 - Hands-free (in car)
 - Speaker Identification
 - Language Identification
 - Second language ('L2') (accent reduction)
 - Audio archive searching

LVCSR

- Large Vocabulary Continuous Speech Recognition
- ~20,000-64,000 words
- Speaker independent (vs. speaker-dependent)
- Continuous speech (vs isolated-word)

Current error rates

Ballpark numbers; exact numbers depend very much on the specific corpus

Task	Vocabulary	Error Rate%
Digits	11	0.5
WSJ read speech	5K	3
WSJ read speech	20K	3
Broadcast news	64,000+	10
Conversational Telephone	64,000+	20

HSR versus ASR

Task	Vocab	ASR	Hum SR
Continuous digits	11	.5	.009
WSJ 1995 clean	5K	3	0.9
WSJ 1995 w/noise	5K	9	1.1
SWBD 2004	65K	20	4

■ Conclusions:

- Machines about 5 times worse than humans
- Gap increases with noisy speech
- These numbers are rough, take with grain of salt

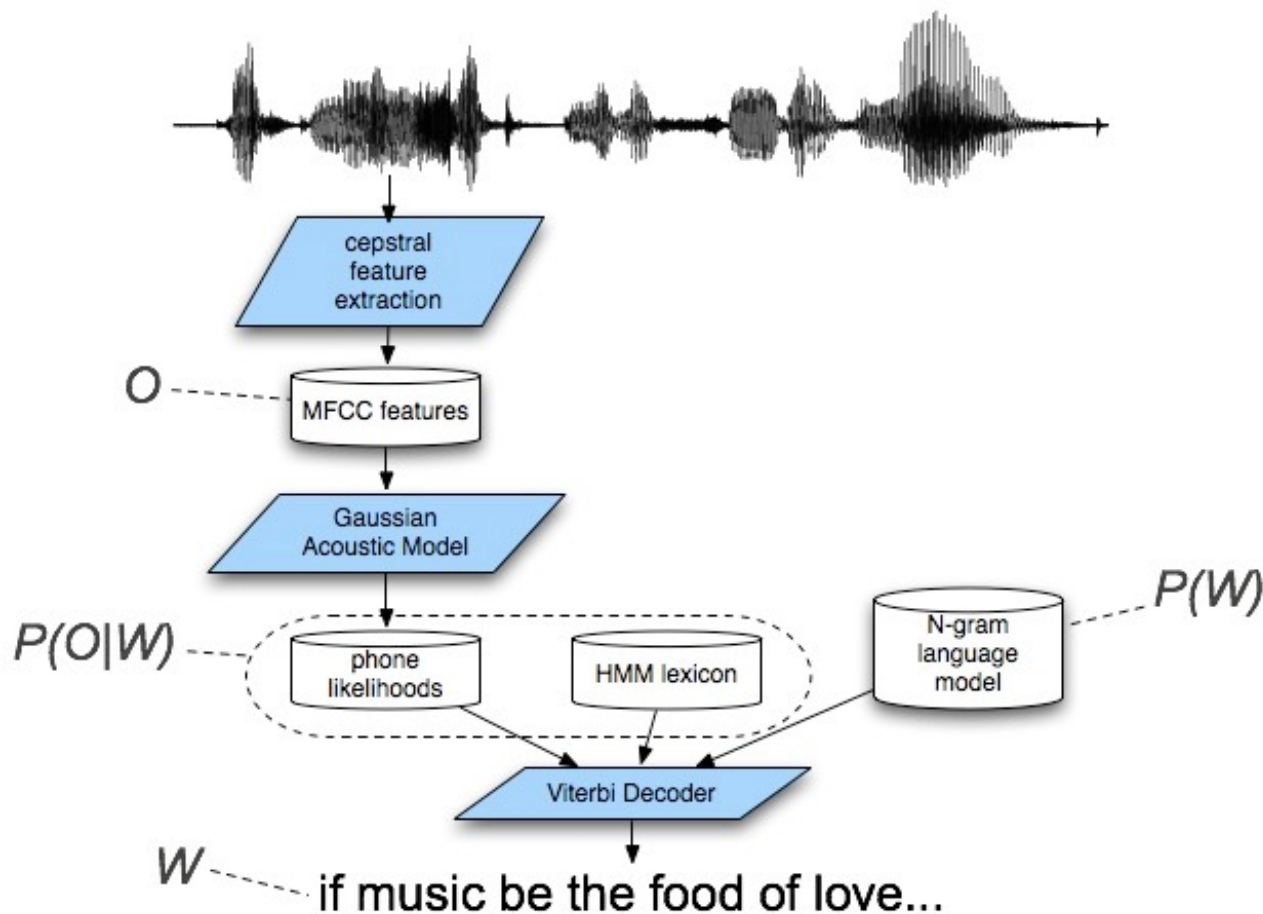

Why is conversational speech harder?

- A piece of an utterance without context
- The same utterance with more context

LVCSR Design Intuition

- Build a statistical model of the speech-to-words process
- Collect lots and lots of speech, and transcribe all the words.
- Train the model on the labeled speech
- Paradigm: Supervised Machine Learning + Search

Speech Recognition Architecture

The Noisy Channel Model

- Search through space of all possible sentences.
- Pick the one that is most probable given the waveform.

The Noisy Channel Model (II)

- What is the most likely sentence out of all sentences in the language L given some acoustic input O ?
- Treat acoustic input O as sequence of individual observations
 - $O = o_1, o_2, o_3, \dots, o_t$
- Define a sentence as a sequence of words:
 - $W = w_1, w_2, w_3, \dots, w_n$

Noisy Channel Model (III)

- Probabilistic implication: Pick the highest prob $S = W$:

$$\hat{W} = \arg \max_{W \in L} P(W | O)$$

- We can use Bayes rule to rewrite this:

$$\hat{W} = \arg \max_{W \in L} \frac{P(O | W)P(W)}{P(O)}$$

- Since denominator is the same for each candidate sentence W , we can ignore it for the argmax:

$$\hat{W} = \arg \max_{W \in L} P(O | W)P(W)$$

Noisy channel model

$$\hat{W} = \arg \max_{W \in L} P(\overset{\text{likelihood}}{\underset{\downarrow}{O}} | W) \overset{\text{prior}}{\underset{\downarrow}{P(W)}}$$

The noisy channel model

- Ignoring the denominator leaves us with two factors: $P(\text{Source})$ and $P(\text{Signal} | \text{Source})$

Speech Architecture meets Noisy Channel

Architecture: Five easy pieces (only 3-4 for now)

- HMMs, Lexicons, and Pronunciation
- Feature extraction
- Acoustic Modeling
- Decoding
- Language Modeling (seen this already)

Lexicon

- A list of words
- Each one with a pronunciation in terms of phones
- We get these from on-line pronunciation dictionary
- CMU dictionary: 127K words
 - <http://www.speech.cs.cmu.edu/cgi-bin/cmudict>
- We'll represent the lexicon as an HMM

HMMs for speech: the word "six"

Phones are not homogeneous!

Each phone has 3 subphones

Resulting HMM word model for "six" with their subphones

HMM for the digit recognition task

Detecting Phones

- Two stages
 - **Feature extraction**
 - Basically a slice of a spectrogram
 - **Phone classification**
 - Using GMM classifier

Discrete Representation of Signal

- Represent continuous signal into discrete form.

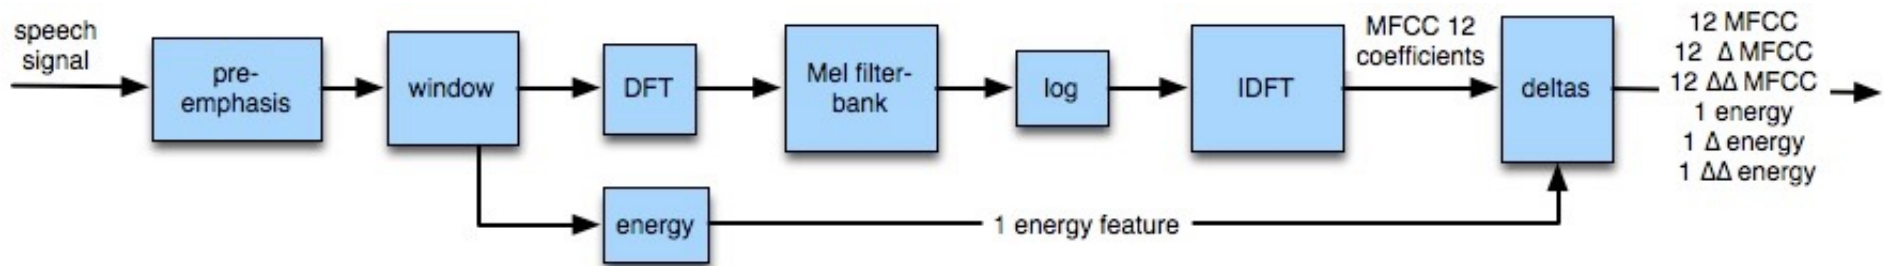

Digitizing the signal (A-D)

■ Sampling:

- measuring amplitude of signal at time t
- 16,000 Hz (samples/sec) Microphone ("Wideband"):
- 8,000 Hz (samples/sec) Telephone
- Why?
 - Need at least 2 samples per cycle
 - max measurable frequency is half sampling rate
 - Human speech $< 10,000$ Hz, so need max 20K
 - Telephone filtered at 4K, so 8K is enough

MFCC: Mel-Frequency Cepstral Coefficients

Pre-Emphasis

- **Pre-emphasis: boosting the energy in the high frequencies**
- Q: Why do this?
- A: The spectrum for voiced segments has more energy at lower frequencies than higher frequencies.
 - This is called **spectral tilt**
 - Spectral tilt is caused by the nature of the glottal pulse
- Boosting high-frequency energy gives more info to Acoustic Model
 - Improves phone recognition performance

Example of pre-emphasis

- Before and after pre-emphasis
 - Spectral slice from the vowel [aa]

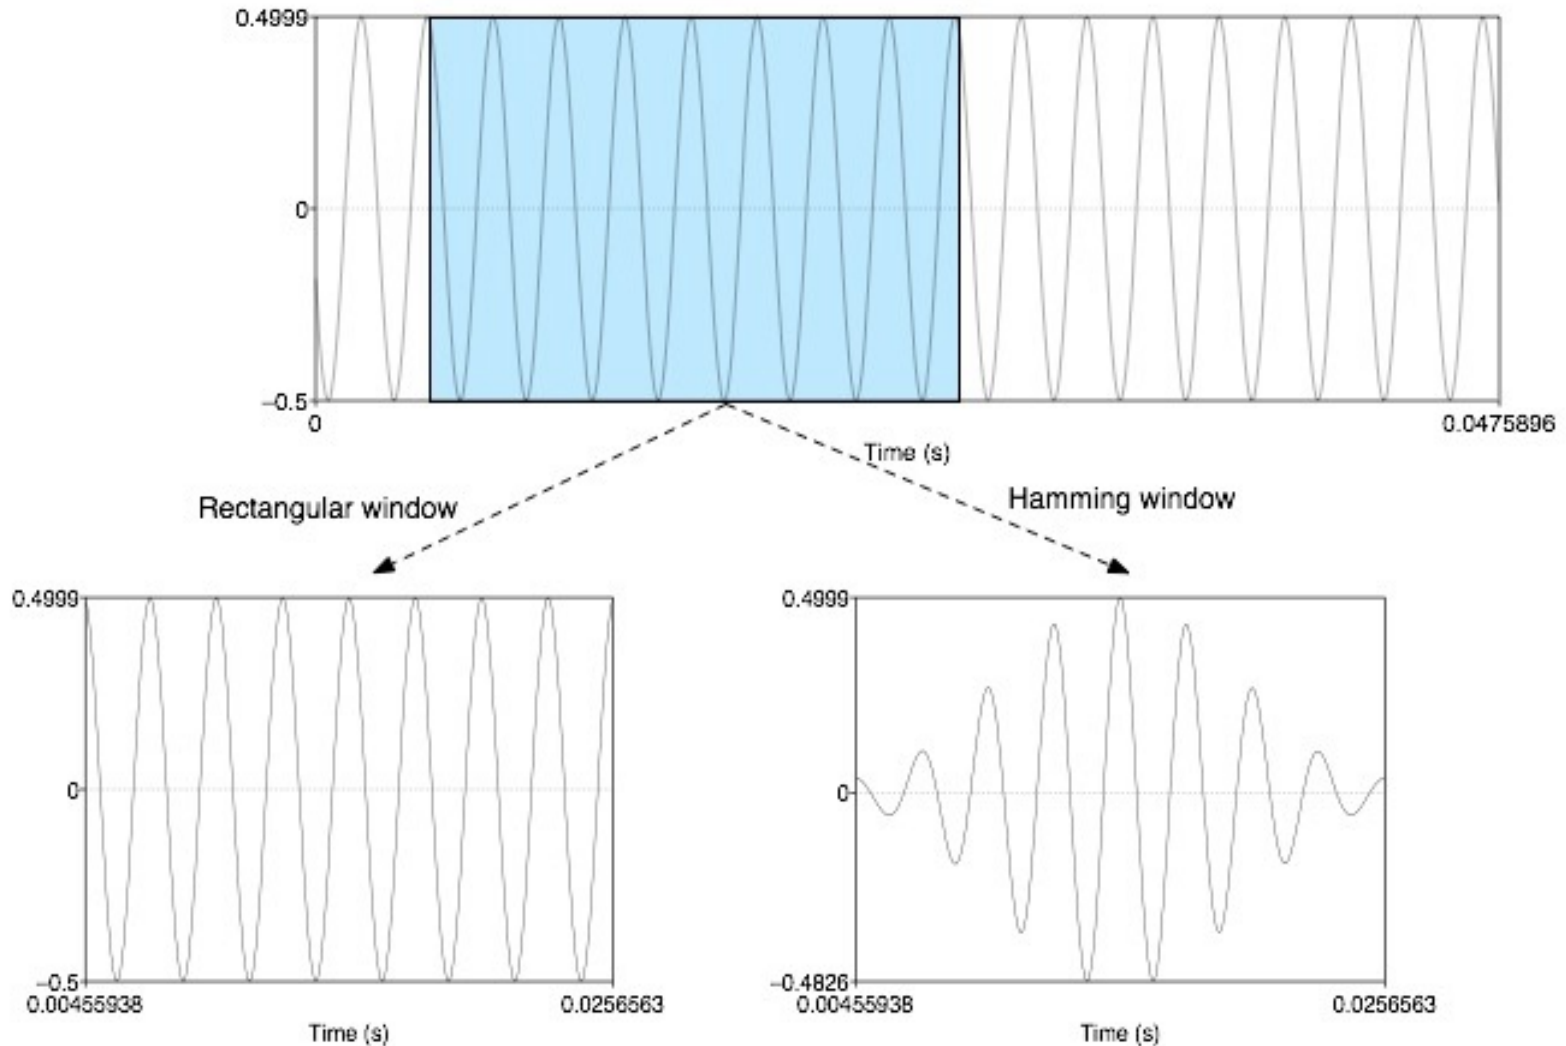

MFCC process: windowing

Windowing

- Why divide speech signal into successive overlapping frames?
 - Speech is not a stationary signal; we want information about a small enough region that the spectral information is a useful cue.
- Frames
 - Frame size: typically, 10-25ms
 - Frame shift: the length of time between successive frames, typically, 5-10ms

MFCC process: windowing

Common window shapes

- Rectangular window:

$$w[n] = \begin{cases} 1 & 0 \leq n \leq L - 1 \\ 0 & \text{otherwise} \end{cases}$$

- Hamming window

$$w[n] = \begin{cases} 0.54 - 0.46 \cos\left(\frac{2\pi n}{L-1}\right) & 0 \leq n \leq L - 1 \\ 0 & \text{otherwise} \end{cases}$$

Discrete Fourier Transform

- **Input:**
 - Windowed signal $x[n] \dots x[m]$
- **Output:**
 - For each of N discrete frequency bands
 - A complex number $X[k]$ representing magnitude and phase of that frequency component in the original signal
- **Discrete Fourier Transform (DFT)**

$$X[k] = \sum_{n=0}^{N-1} x[n] e^{-j2\frac{\pi}{N}kn}$$

- **Standard algorithm for computing DFT:**
 - Fast Fourier Transform (FFT) with complexity $N \cdot \log(N)$
 - In general, choose $N=512$ or 1024

Discrete Fourier Transform computing a spectrum

- A 25 ms Hamming-windowed signal from [iy]
 - And its spectrum as computed by DFT (plus other smoothing)

Mel-scale

- Human hearing is not equally sensitive to all frequency bands
- Less sensitive at higher frequencies, roughly > 1000 Hz
- I.e. human perception of frequency is non-linear:

Mel-scale

- A **mel** is a unit of pitch

Pairs of sounds perceptually equidistant in pitch
Are separated by an equal number of mels

- Mel-scale is approximately linear below 1 kHz and logarithmic above 1 kHz
- Definition:

$$Mel(f) = 2595 \log_{10} \left(1 + \frac{f}{700} \right)$$

Log energy computation

- Log of the square magnitude of the output of the mel filterbank
- Why log?
 - Logarithm compresses dynamic range of values
 - Human response to signal level is logarithmic
 - humans less sensitive to slight differences in amplitude at high amplitudes than low amplitudes
 - Makes frequency estimates less sensitive to slight variations in input (power variation due to speaker's mouth moving closer to mike)
- Why square?
 - Phase information not helpful in speech

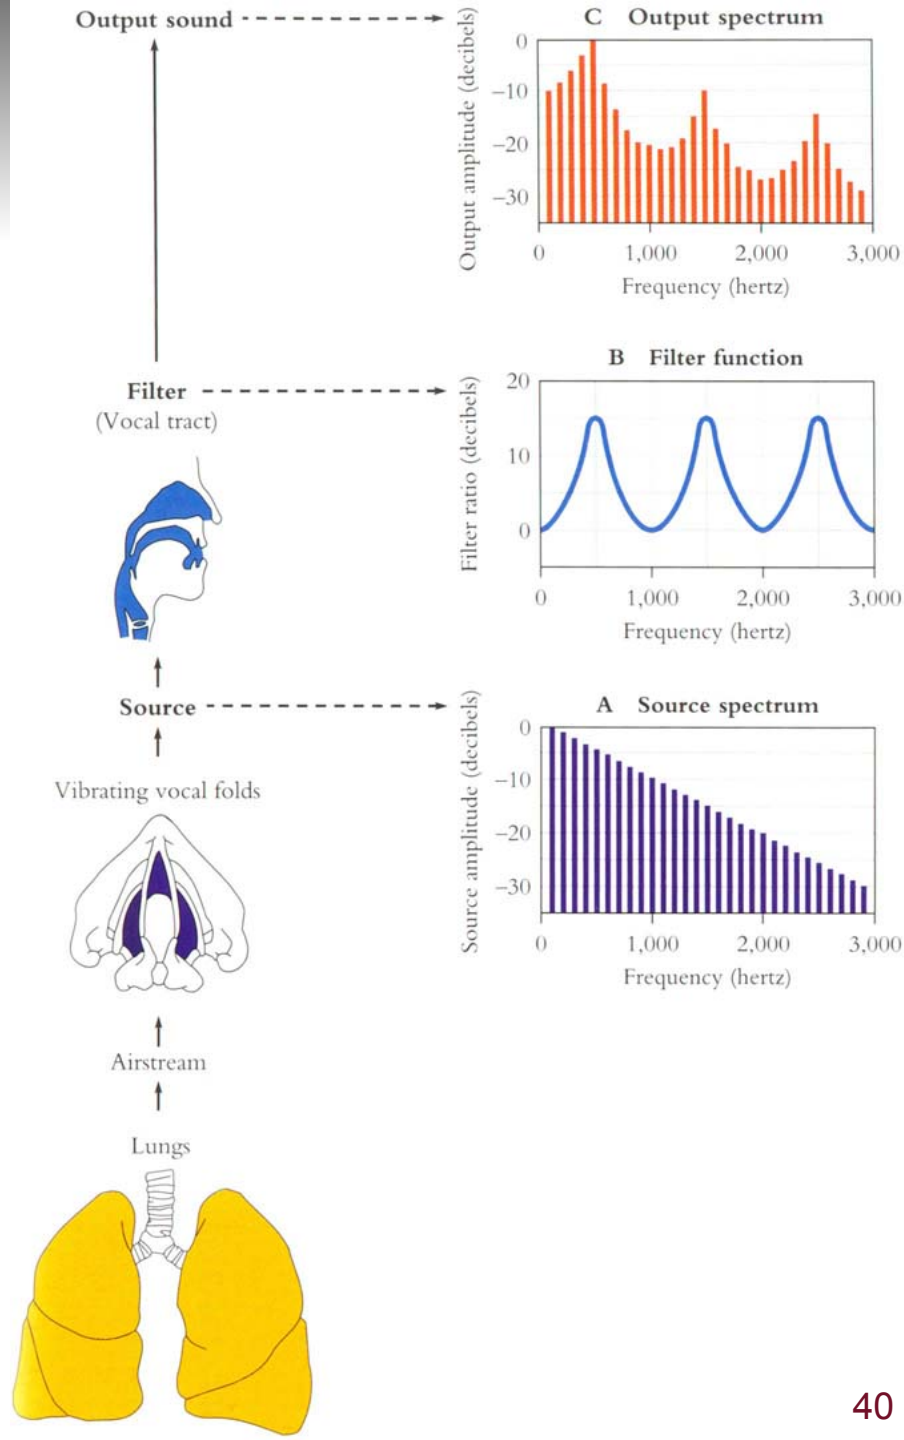

The Cepstrum

- One way to think about this
 - Separating the **source** and **filter**
 - Speech waveform is created by
 - A glottal source waveform
 - Passes through a vocal tract which because of its shape has a particular filtering characteristic
- Articulatory facts:
 - The vocal cord vibrations create harmonics
 - The mouth is an amplifier
 - Depending on shape of oral cavity, some harmonics are amplified more than others

Vocal Fold Vibration

George Miller figure

We care about the filter not the source

- Most characteristics of the source
 - F0
 - Details of glottal pulse
- Don't matter for phone detection
- What we care about is the **filter**
 - The exact position of the articulators in the oral tract
- So we want a way to separate these
 - And use only the filter function

The Cepstrum

- The spectrum of the log of the spectrum

Spectrum

Log spectrum

Spectrum of log spectrum

Thinking about the Cepstrum

Mel Frequency cepstrum

- The cepstrum requires Fourier analysis
- But we're going from frequency space back to time
- So we actually apply inverse DFT

$$y_t[k] = \sum_{m=1}^M \log(|Y_t(m)|) \cos(k(m - 0.5)\frac{\pi}{M}), \quad k=0,\dots,J$$

- Details for signal processing gurus: Since the log power spectrum is real and symmetric, inverse DFT reduces to a Discrete Cosine Transform (DCT)

Another advantage of the Cepstrum

- DCT produces highly **uncorrelated** features
- We'll see when we get to acoustic modeling that these will be much easier to model than the spectrum
 - Simply modelled by linear combinations of Gaussian density functions with diagonal covariance matrices
- In general we'll just use the first 12 cepstral coefficients (we don't want the later ones which have e.g. the F0 spike)

Dynamic Cepstral Coefficient

- The cepstral coefficients do not capture energy

- So we add an energy feature $Energy = \sum_{t=t_1}^{t_2} x^2[t]$

- Also, we know that speech signal is not constant (slope of formants, change from stop burst to release).

- So we want to add the changes in features (the slopes).

- We call these **delta** features

- We also add **double-delta** acceleration features

Typical MFCC features

- Window size: 25ms
- Window shift: 10ms
- Pre-emphasis coefficient: 0.97
- MFCC:
 - 12 MFCC (mel frequency cepstral coefficients)
 - 1 energy feature
 - 12 delta MFCC features
 - 12 double-delta MFCC features
 - 1 delta energy feature
 - 1 double-delta energy feature
- Total 39-dimensional features

Why is MFCC so popular?

- Efficient to compute
- Incorporates a perceptual Mel frequency scale
- Separates the source and filter
- IDFT(DCT) decorrelates the features
 - Improves diagonal assumption in HMM modeling

Coming up: Acoustic Modeling (= Phone detection)

- Given a 39-dimensional vector corresponding to the observation of one frame o_i
- And given a phone q we want to detect
- Compute $p(o_i|q)$
- Most popular method:
 - GMM (Gaussian mixture models)
- Other methods
 - Neural nets, CRFs, SVM, etc

Summary

- ASR Architecture
 - The Noisy Channel Model
- Five easy pieces of an ASR system
 - 1) Language Model
 - 2) Lexicon/Pronunciation Model (HMM)
 - 3) Feature Extraction
 - 4) Acoustic Model
 - 5) Decoder
- Training
- Evaluation
